Fundamentals of Airborne Radar Systems

What is Radar?

Radar, an acronym for Radio Detection and Ranging, is a system that uses radio waves to detect objects and measure their distance, speed, and other characteristics. It involves transmitting electromagnetic waves toward targets and analyzing the echoes that bounce back.

Basic Principles of Radar Operation

The core working principle of radar involves three main steps:

- Transmission: The radar system emits a burst of radio waves via its antenna.
- Propagation: These waves travel through the atmosphere at the speed of light.
- Reflection and Reception: When waves encounter an object, they reflect back toward the radar antenna. The system then receives and processes these echoes to determine target information.

Why Airborne Radar?

Airborne radar systems are mounted on aircraft, helicopters, drones, or missiles, providing a mobile platform for:

- Terrain mapping
- Weather monitoring

- Surveillance and reconnaissance
- Navigation aid
- Target tracking in military contexts

The mobility allows for rapid deployment over vast or inaccessible areas, offering real-time data critical for decision-making.

Components of an Airborne Radar System

- Continuous Wave (CW) Radar: Transmits a constant signal, primarily used for velocity detection via Doppler effect.

Range Measurement

The distance to a target is determined by measuring the time interval between transmission and the reception of the echo:

$$ \text{Range} = \frac{c \times t}{2} $$

where:

- $ c $ = speed of light (~3 x 10^8 m/s)
- $ t $ = time delay between transmitted pulse and received echo

Velocity Detection

Using the Doppler effect, radar can measure the relative speed of a target based on the frequency shift of the returned signal.

Angular Detection

Rotation or electronic steering of the antenna allows the system to determine the azimuth and elevation angles of detected objects.
